Abstract: The GRASP/Ada project (Graphical Representations of Algorithms, Structures, and Processes for Ada) has successfully created and prototyped a new algorithmic level graphical representation for Ada software, the Control Structure Diagram (CSD). The primary impetus for creation of the CSD was to improve the comprehension efficiency of Ada software and thus improve reliability and reduce costs. The emphasis has been on the automatic generation of the CSD from Ada source code to support reverse engineering and maintenance. The CSD has the potential to replace traditional prettyprinted Ada source code. In Phase 1 of the GRASP/Ada project, the CSD graphical constructs were created and applied manually to several small Ada programs. A prototype (Version 1) was designed and implemented using FLEX and BISON running under VMS on a VAX 11-780. In Phase 2, the prototype was improved and ported to the Sun 4 platform under UNIX. A user interface was designed and partially implemented using the HP widget toolkit and X Windows. The prototype was applied successfully to numerous Ada programs ranging in size from several hundred to several thousand lines of source code. In Phase 3 of the project, the prototype was prepared for limited distribution (GRASP/Ada Version 3.0) to facilitate evaluation. The user interface was extensively reworked using the Athena widget toolkit and X Windows. The current prototype provides the capability for the user to generate CSD from Ada source code in a reverse engineering mode with a level of flexibility suitable for practical application.
ACKNOWLEDGEMENTS

We appreciate the assistance provided by NASA personnel, especially Mr. Keith Shackelford whose guidance has been of great value. Portions of this report were contributed by each of the members of the project team. The following is an alphabetical listing of the project team members.

1.0 Introduction and Executive Summary

Computer professionals have long promoted the idea that graphical representations of software can be extremely useful as comprehension aids when used to supplement textual descriptions and specifications of software, especially for large complex systems. The general goal of this research has been the investigation, formulation and generation of *graphical representations of algorithms, structures, and processes for Ada* (GRASP/Ada). This task, in which we described and categorized various graphical representations that can be extracted or generated from source code, has focused on *reverse engineering*.

Reverse engineering normally includes the processing of source code to extract higher levels of abstraction for both data and processes. The primary motivation for reverse engineering is increased support for software reusability, verification, and software maintenance, all of which should be greatly facilitated by automatically generating a set of "formalized diagrams" to supplement the source code and other forms of existing documentation. For example, Selby [SEL85] found that code reading was the most cost effective method of detecting errors during the verification process when compared to functional testing and structural testing. And Standish [STA85] reported that program understanding may represent as much as 90% of the cost of maintenance. Hence, improved comprehension efficiency resulting from the integration of graphical notations and source code could have a significant impact on the overall cost of software production. The overall goal of the GRASP/Ada project is to provide the foundation for a CASE (computer-aided software engineering) environment in which reverse engineering and forward engineering (development) are tightly coupled. In this environment, the user may specify the software
in a graphically-oriented language and then automatically generate the corresponding Ada code [ADA83]. Alternatively, the user may specify the software in Ada or Ada/PDL and then automatically generate the graphical representations either dynamically as the code is entered or as a form of post-processing.

Figure 1 provides an overview to the three phases of the GRASP/Ada project. Ada source code or PDL is depicted as the starting point for application of the GRASP/Ada toolset. Each phase is briefly described below in the order that diagrams might be generated in a typical reverse engineering scenario.

1.1 Phase 1 - The Control Structure Diagram For Ada

Phase 1 concentrated on a survey of graphical notations for software and the development of a new algorithmic or PDL/code level diagram for Ada. Tentative graphical control constructs for the Control Structure Diagram (CSD) were created and initially prototyped in a VAX/VMS environment. This included the development of special diagramming fonts for both the screen and printer and the development of parser and scanner using UNIX based tools such as LEX and YACC. Appendix B provides a detailed description of the CSD and the rationale for its development. The final report for Phase 1 [CRO89] contains a complete description of all accomplishments of Phase 1.

1.2 Phase 2 - The GRASP/Ada Prototype and User Interface

During Phase 2, the prototype was extended and ported to a Sun/UNIX environment. The development of a user interface based on the X Window System represented a major part of the extension effort. VerdiX Ada and the VerdiX DIANA interface were acquired as potential commercial tools upon which to base the GRASP/Ada prototype. Architectural

Prototype Integration
diagrams for Ada were surveyed and the OOSD notation [WAS89] was identified as having the best potential for accurately representing many of the varied architectural features of an Ada software system. Phase 2 also included the preliminary design and a separate exploratory prototype for an architectural CSD. The best aspects of architectural CSD are expected to be integrated into the fully operational GRASP/Ada prototype during a future phase of the project. The final report for Phase 2 [CRO90c] contains a complete description of the accomplishments of Phase 2.

1.3 Phase 3 - CSD Generation Prototype and Preliminary Object Diagram Prototype

Phase 3 has had two major thrusts: (1) completion and limited release of an operational GRASP/Ada prototype which generates CSDs and (2) the development of a preliminary prototype which generates object diagrams directly from Ada source code. Completion of the GRASP/Ada CSD prototype (CSDgen) included the addition of substantial functionality, via the User Interface, to make the prototype easier to use. CSDgen was installed and demonstrated on a Sun workstation at Marshall Space Flight Center, Alabama in September 1991. It is currently installed and in use in several software engineering courses at Auburn University. The latter, in particular, is providing information for evaluation prior to widespread release to teaching and research communities, business, and industry. To date, over 100 requests for information regarding GRASP/Ada have been received as a result of publications generated from this research. Responding to these requests is an important element of the ongoing evaluation and refinement of the GRASP/Ada reverse engineering system.

The development of a preliminary prototype for generating architectural object diagrams (ODgen) for Ada source/PDL has been an effort to determine feasibility rather than
to deliver an operational prototype as was the case with CSD generator above. The preliminary prototype has indicated that the development of the components to recover the information to be included in the diagram, although a major effort, is relatively straightforward. However, the research has also indicated that the major obstacle for automatic object diagram generation is the automatic layout of the diagrams in a human readable and/or aesthetically pleasing format. A user extensible rule base, which automates the diagram layout task, is expected to be formulated during future GRASP research. Interactive Development Environment’s Software through Pictures (IDE/StP), which supports the OOSD notation in a forward engineering sense, has been identified as a candidate for a commercial CASE environment with which to integrate GRASP/Ada reverse engineering system.

The following sections of this report describe the overall GRASP/Ada system model, the control structure diagram generator, the user interface, the library, the object diagram generator, and future requirements. Appendix A contains paper entitled "Reverse Engineering" which has been accepted for publication in Advances in Computing. This paper, which was written during Phases 2 and 3, provides a taxonomy of reverse engineering and comprehensive review of the current literature. Appendix B contains a paper entitled "Control Structure Diagrams for Ada," published in Journal of Pascal, Ada & Modula 2. This paper, which was written during Phase 1, describes the overall rationale for the development of the CSD. Appendix C contains a CSD produced from Ada source code provided by Marshall Space Flight Center. Appendix D contains the MAN-page which describes each of its the current options.
2.0 The System Model

The general system model for the GRASP/Ada prototype is described in this section. The overall functionality of the system is briefly described from a data flow perspective and then each of the GRASP/Ada components is presented in the form of a system block diagram.

2.1 GRASP/Ada System Data Flow

Figures 2 describes the context and overall flow of information to and from the GRASP/Ada system. The primary input is Ada source code and GRASP commands and the primary outputs are control structure diagrams, object diagrams and library information. The Ada source code is assumed to be syntactically correct.

Figure 3 describes the major processes and overall flow of information within the GRASP/Ada system. Process 1 parses Ada source code and produces a parse tree, comments, symbolic and unit information. Process 2 produces CSD files as CSDgen action routines are called during the parse in Process 1. Process 3 produces object diagrams from symbolic and unit information. Processes 4 and 5 produce screen and printer images of control structure diagrams and object diagrams from intermediate files via the user interface when appropriate commands are received.

2.2 GRASP/Ada System Block Diagram

Figure 4 depicts the major system components hierarchically to illustrate the layers and component interfaces. The user interface (not shown in the system data flow diagram) was built using the X Window System and provides general control and coordination among
Figure 2. GRASP/Ada Context Level Data Flow Diagram
Figure 3. GRASP/Ada System Level Data Flow Diagram
Figure 4. GRASP/Ada System Block Diagram
the other components.

The control structure diagram generator, CSDgen, has its own parser/scanner built using FLEX and BISON, successors of LEX and YACC. It also includes its own printer utilities. As such, CSDgen is a self-sufficient component which can be used from the user interface or the command line without the commercial components. When changes are made to the Ada source code or PDL, currently the user must modify the original source file rather than the generated CSD file. The entire file must be reparsed to produce an updated CSD. A CSD editor (CSDedit), which will provide for dynamic incremental modification of the CSD, is currently in the planning stages.

The object diagram generation component, ODgen, is in the analysis phase and has been implemented as a separate preliminary prototype. The shading indicates planned integration. The feasibility of automatic diagram layout remains under investigation. Beyond automatic diagram layout, several design alternatives have been identified. The major alternatives include the decision of whether to attempt to integrate GRASP/Ada directly with commercial components, namely (1) the Veridex Ada development system (VADS) and DIANA interface for extraction of diagram information and (2) IDE’s Software through Pictures, Ada Development Environment (IDE/StP/ADE) for the display of the object diagrams. Each of these components are indicated in Figure 4.

The GRASP/Ada library component, GRASPlib, provides for coordination of all generated items with their associated source code. Its purpose is to facilitate navigation among the diagrams and the production of sets of diagrams. Both CSDgen and ODgen produce library entries as Ada source is processed. Currently, these consists of directories of UNIX files with identifying extensions.
In the following sections, the general functional requirements and prototype implementation are described for each of the major GRASP/Ada components: the control structure diagram generator, the user interface, and the object diagram generator.
3.0 Control Structure Diagram Generator

The GRASP/Ada control structure diagram generator (CSDgen) is described in this section. The rationale for the development of the CSD, which has been detailed in previous reports [CRO89, CRO90c], is summarized in Appendix B. Examples of the CSD are presented in conjunction with the User Interface in Section 4.0 and in Appendix C, Extended Examples. The UNIX MAN-page description of the options is contained in Appendix D.

3.1 Generating the CSD

The primary function of CSDgen is to produce a CSD for a corresponding Ada source file. The graphical constructs produced by CSDgen are summarized in Figure 5. CSDgen has its own parser/scanner constructed using LEX/YACC based software tools available with UNIX. Although a complete parse is done during CSD generation, CSDgen assumes the Ada source code has been previously compiled and thus is syntactically correct. Currently, little error recovery is attempted when a syntax error is encountered. The diagram is simply generated down to the point of the error. The current CSDgen prototype builds the diagram directly during the parse by inserting CSD graphics characters into a file along with text. To increase efficiency and improve extensibility, future versions of the CSDgen prototype will use a more abstract intermediate representation.

Since GRASP/Ada is expected to be used to process and analyze large existing Ada software systems consisting of perhaps hundreds of files, an option to generate all the CSDs at once is provided. Generating a set of CSDs is facilitated by entering *.a or some other
Figure 5. Control Structure Diagram Constructs
wildcard with a conventional source file extension, for the file name. A CSD generation summary window displays the progress of the generation by listing each file as it is being processed and any resulting error messages. The summary concludes with number of files processed and the number of errors encountered. The default for each CSD file name is the source file name with .csd appended. If an error is encountered, an extension of .err is used. As the CSDs are generated, the GRASP library is updated, which currently consists of populating a specified directory with file images of the CSDs. Generating a set of CSDs can be considered a user interface requirement rather than strictly a CSD generator requirement.

3.2 Displaying the CSD - Screen and Printer

Basic display capabilities to the screen and printer were implemented during Phase 2. Screen display is facilitated by sending the CSD file to a CSD window opened under an X Window manager. Printing is accomplished by converting the CSD file to a PostScript file and then sending it to a printer. Moving to a more abstract intermediate representation in future versions will necessitate the development of a new set of display routines which will be X Window System based. However, these new routines will increase the flexibility and capability of CSDgen, thus making it more immediately useful to the research community.

CSD Screen Fonts. The default CSD screen font is a bitmap 14 point Courier to which the CSD graphic characters have been added. The font was defined as a bitmap distribution font (BDF) then converted to SNF format required by the X Window System. Four additional screen fonts ranging from 5 to 18 point are user selectable.

CSD Printer Fonts. CSD Printer fonts were initially developed for the HP LaserJet series. These were then implemented as PostScript type 3 fonts and all subsequent font
development has been directed towards the PostScript font. The PostScript font provides the most flexibility since its size is user selectable from 1 to 300 points.

3.3 Displaying the CSD - Future Considerations

**Layout/Spacing.** The general layout of the CSD is highly structured by design. However, the user should have control over such attributes as horizontal and vertical spacing and the optional use of some diagramming symbols. In the current Version 3 CSDgen prototype, horizontal and vertical spacing are not user selectable. They are a part of the CSD file generation and are defaulted to single spacing with 80 characters per line. In order to change these, e.g., from single to double spacing, the CSD file would have to be regenerated. In future versions of the prototype, these options will be handled by the new display routines and, as such, can be modified dynamically without regenerating the CSD file.

Vertical spacing options will include single, double, and triple spacing (default is single). Margins will be roughly controlled by the character line length selected, either 80 or 132 characters per line (default is 80). Indentation of the CSD constructs has been a constant three blank characters. Support for variable margins and indentation is being investigated in conjunction with the new display routines. In addition, several display options involving CSD graphical constructs are under consideration. For example, the boxes drawn around procedure and task entry calls may be optionally suppressed to make the diagram more compact.

**Collapsing the CSD.** The CSD window should provide the user with the capability to collapse the CSD based on all control constructs as well as complete diagram entities (e.g., procedures, functions, tasks and packages). This capability directly combines the ideas of chunking with control flow which are major aids to comprehension of software. An
architectural CSD (ArchCSD) [DAV90] can be facilitated by collapsing the CSD based on procedure, function, and task entry calls, and the control constructs that directly affect these calls. The initial ArchCSD prototype was completely separate from CSDgen and required complete regeneration of the ArchCSD file for each option. In future versions of the prototype, the ArchCSD will be generated by the display routines from the single intermediate representation of the CSD.

**Color.** Although general color options such as background and foreground may be selected via the X Windows system, color options within a specific diagram were only briefly investigated for both the screen and printer. It was decided that these will not be pursued in the Version 3 prototype.

**Printing An Entire Set of CSDs.** Printing an entire set of CSDs in an organized and efficient manner is an important capability when considering the typically large size of Ada software systems. A book format is under consideration which would include a table of contents and/or index. In the event GRASP/Ada is integrated with IDE/StP/ADE, the StP Document Preparation System could possibly be utilized for this function.

### 3.4 Incremental Changes to the CSD

In the present prototype, there is no capability for editing or incrementally modifying the CSD. The source code is modified using a text editor and then the CSD is regenerated. While this has been sufficient for early prototyping, especially for small programs, editing capabilities are desirable in an operational setting. An editor has been proposed and is briefly discussed in Section 7.0 Future Requirements.
3.5 Navigating Through Large CSDs - Alternatives

Index (or Table of Contents). An index, similar to that presented in the Xman application provided with the X Window System for viewing manual pages, is used to navigate among a system of CSDs. The user clicks on the index entry and the corresponding CSD is displayed. The index entries would be created as CSDs are generated and stored in the GRASP/Ada library. Entries in the library are to include procedures, functions, tasks, task entries, and packages. See Section 6 below for details.

Direct Navigation Via CSD. The user is allowed to click on procedure, function, and task entry calls in the CSD directly and a separate CSD window is opened containing the selected CSD or fragment thereof. Two potential problems have been identified with this approach. Using the mouse for selection may conflict with established editing functions supported by the mouse. In addition, it may be difficult to relate the characters or CSD graphical construct with subprogram and entry names. The availability of middle mouse button for this purpose is being investigated.

3.6 Internal Representation of the CSD - Alternatives

Several alternatives are under consideration for the internal representation of the CSD in the Version 3 prototype. Each has its own merits with respect to processing and storage efficiency and is briefly described below.

Single ASCII File with CSD Characters and Text Combined. This is the most direct approach and is currently used in the version 2 prototype. The primary advantage of this approach is that combining the CSD characters with text in a single file eliminates the need for elaborate transformation and thus enables the rapid implementation of prototypes as was the case in the previous phases of this project. The major disadvantages of this approach
are that it does not lend itself to incremental changes during editing and the CSD characters have to be stripped out if the user wants to send the file to a compiler.

**Separate ASCII Files for CSD Characters and Text.** In this approach, the file containing the CSD characters along with placement information would be "merged" with the prettyprinted source file. The primary advantage of this approach is that the CSD characters would not have to be stripped out if the user wants to send the file to a compiler. The major disadvantage of this approach is that coordinating the two files would add complexity to generation and editing routines with little or no benefit. As a result, this approach would be more difficult to implement than the single file approach and not provide the advantages of the next alternative.

**Single ASCII File Without Hard-coded CSD Characters.** This approach represents a compromise between the previous two. While it uses a single file, only "begin construct" and "end construct" codes are actually required for each CSD graphical construct in the CSD file rather than all CSD graphics characters that compose the diagram. In particular, no continuation characters would be included in the file. These would be generated by the screen display and print routines as required. The advantages of this approach would be most beneficial in an editing mode since the diagram could grow and shrink automatically as additional text/source code is inserted into the diagram. The extent of required modifications to text edit windows must be considered with this alternative.

**Direct Generation From DIANA Net.** If tight coupling and integration with a commercial Ada development system such as Verdim VADS is desired, then direct generation of the CSD from the DIANA net produced as a result of compilation could be performed. This would require a layer of software which traverses the DIANA net and calls the appropriate CSD primitives as control nodes are encountered. This approach would
apparently eliminate the possibility of directly editing the CSD since the DIANA interface does not support modifying the net, only reading it.

3.7 Additional CSD Constructs - Alternatives

The following CSD constructs are under consideration for future versions of the prototype.

Generic Task and Package. Dashed task and package symbols should be used to distinguish between generic and non-generic tasks and between generic and non-generic packages.

Function Call. A CSD symbol similar to that used for procedure calls should be used for function calls for consistency.
4.0 User Interface

GRASP/Ada user interface was developed using the X Window System, Version 11 Release 4 (X11R4). The X Window System, or simply X, meets the GRASP/Ada user interface requirements of an industry-standard window based environment which supports portable graphical user interfaces for application software. Some of the key features which make X attractive for this application are its availability on a wide variety of platforms, unique device independent architecture, adaptability to various user interface styles, support from a consortium of major hardware and software vendors, and low acquisition cost. With its unique device independent architecture, X allows programs to display windows on any hardware that supports the X Protocol. X does not define any particular user interface style or policy, but provides mechanisms to support many various interface styles.

The Version 3 prototype user interface is a significant extension of Version 2. It allows the user to open one or more source windows to read or edit source code in the usual way. The user may open one or more CSD windows, indicate corresponding source files and CSD files, and then generate the CSD from each of the indicated source files. If the CSD was generated previously, the source file is not required by the CSD window. In either case, the CSD window allows the user to scroll through the CSD.

The specifications and figures that follow are intended to define the look and feel of the GRASP/Ada User Interface as well as indicate much of its current and future functionality. The Ada source code used in the figures was extracted from the AERO.DAP.PACKAGE provided by NASA to test the CSD generator. Complete CSDs for
the files processed are included in Appendix C. For a complete description of the options available through the user interface, see the MAN-page in Appendix E.

4.1 System Window

The System window, shown in Figure 6, provides the user with the overall organization and structure of the GRASP/Ada tool. Option buttons include: General, Source Code, and Control Structure Diagram. These are briefly described below. A future button is planned for Object Diagram.

General - This option provides access to the environment including loading of fonts for X and selection of printers.

Source Code - This option allows the user to open one or more windows for viewing and editing source code.

Control Structure Diagram - This option allows the user to open one or more windows for viewing CSDs.

Help - This option opens a window containing a summary of the CSD graphical constructs. The user may scroll the combined display or selectively display individual constructs.

4.2 Source Window

The Source window, shown in Figure 7, provides the user with the general capabilities of a text editor. It is included in the GRASP/Ada system for completeness since the system uses source code as its initial input. The user may elect to use any suitable editor callable from the X environment. A future version of GRASP/Ada will allow the user to edit the CSD directly, making a pure text editor redundant.

        end if;

    end STAB_AXES_CMD;

end STAB_AXES_CMD_PACKAGE;
The source file and its associated directory path are displayed in the top pane of each window. See the Control Structure Diagram Window below for details on the menu options.

4.3 Control Structure Diagram Window

The Control Structure Diagram window, shown in Figure 8, provides the user with capabilities for generating and viewing a CSD for an Ada source file. Multiple CSD windows may be opened to access several CSD files at once. CSD file names and their associated directory paths are entered and displayed at the top of each window. When the CSD window is opened initially, the source file with a .csd extension is displayed as the default. In the current version of GRASP/Ada, generation of the CSD is done on a file-level basis where each file contains one or more units. When changes are made to the source code, the entire CSD for the file involved must be regenerated. Future versions of GRASP/Ada will address incremental regeneration of the CSD in conjunction with editing capabilities in the CSD window. The CSD window options are described below.

File - This option allows the user to select from numerous options including:

Load - This option loads a CSD file. A window is presented to the user that allows the user to select a file from current directory (see Figure 9).

Open Source - This is a future option which opens a source window with the source file that corresponds to the current CSD file. The purpose of this option is to facilitate editing of the source file in the absence of CSD editing capabilities in the CSD window.

Generate CSD - This is a future option which will facilitate regenerating the CSD from an existing CSD. The CSD graphics characters must be filtered prior to the parse.
Compile - This is a future option to allow an Ada compiler to be called from the CSD window.

Save - This option saves the CSD file with the same name as was loaded.

Save as ... - This option saves the CSD file with a new name.

Print - A window is presented which allows the user to select various print options such as point size, page numbers, and header.

Quit - The CSD window is closed.

View - (not implemented) This option will allow the user to select from options including: Enable Collapse (Disable Collapse), Suppress CSD (Show CSD), Open TOC window, and Open Index window.

Enable Collapse (Disable Collapse) - This option will allow the user to collapse the CSD based on its control constructs.

Suppress CSD (Show CSD) - This option will allow the user to suppress or hide the CSD giving the appearance of prettyprinted code.

Open TOC Window - This option will access the GRASP library and displays a table of contents based on Ada scoping.

Open Index Window - This option will access the GRASP library and display an index of units in alphabetical order.

Find - (not implemented) This option will allow the user to perform search and replace operations. Currently, this is a proposed future option which may become an integral function of the CSD window when editing capabilities are added.
4.4 Help Window

The Help Window provides the user with the capability to display and print templates of the CSD constructs. The user may select individual CSD constructs from a menu as illustrated in Figure 10 with the RENDEZVOUS construct. Alternatively, the user may select the DISPLAY ALL CSD CONSTRUCTS option, as shown in Figure 11, and then scroll through the constructs alphabetically.

Funded, in part, by Marshall Spe...
5.0 The GRASP Library

The GRASP library provides the overall organization of the generated diagrams. The current file organization uses standard UNIX directory conventions as well as default naming conventions. For example, all Ada source files end in .a or .ada, the corresponding CSD files end in .a.csd, and the corresponding print files end in .a.csd.ps. In the present prototype, library complexity has been keep to a minimum by relying on the UNIX directory organization. In future versions, a GRASP library entry will be generated for each procedure, function, package, task, task entry, and label. The library entry will contain minimally the following fields.

identifier - note: unique key should be composed of the identifier + scoping.

scoping/visibility

type (procedure, function, etc.)

parameter list - to aid in overload resolution.

source file (file name, line number) - note: the page number can be computed from the line number.

CSD file (file name, line number)

OD file (file name)

"Referenced by" list

"References to" list

Alternatives for generation and updating of the library entries include the following.

(1) During CSD generation, the library entry is established and the entry is updated on subsequent CSD generations.
During the processing of DIANA nets.

Alternatives for implementing the GRASP library include (1) developing an Ada package or equivalent C module which is called by the CSD generation routines during the parse of the Ada source, (2) using the VADS library system along with DIANA, and (3) using the StP TROLL/USE relational database system. Of these alternatives, the first one may be the most direct approach since it would be the easiest to control. The VADS and StP library approaches may be more useful with the addition of object diagram generation and also with future integration of GRASP with commercial CASE tools.
6.0 Object Diagram Generator

The object diagram generator (ODgen), produces object diagrams (ODs) for a corresponding set of Ada source files. The requirements specifications and current issues and alternatives are described below. A preliminary prototype has been constructed to determine several of the feasibility issues. Since the Ada package construct captures the essence of the "object" in object-oriented design, the current work has focused on the automatic generation of the package symbol.

6.1 ODgen Symbol Set

The OOSD notation [WAS89] has been selected as a basis for the Object Diagram generator (ODgen). The complete set, which was designed with the intention of using it in forward engineering, is illustrated in Figure 12. In this section, the feasibility of deriving each of these symbols during a reverse engineering effort is considered, and the modifications or supplements needed to render them suitable for the ODgen project are discussed.

Lexical Inclusion of Data Modules. The inclusion of a data module into another module may be determined from a parse of the Ada source code. If a data module is considered to be a component which contains no executable statements other than initializations, then there should be no difficulty in recognizing these modules, and their inclusion in an OD should cause no problems.

Iterative Calls to Library Modules. Again, this information may be extracted from a parse of the Ada source code. There should be no difficulty in producing an OD representation for iterative calls to library modules; however, the composition of this situation
Figure 12. The OOSD Notation Symbol Set
(from Introduction to StP OOSD Graphical Editor, IDE, 1989, p. 59)
with others, such as conditional module calls, may require further analysis.

**Conditional Module Calls.** A conditional call of one module from another can be recognized during parsing, but the generation of an OD representation may prove difficult should the conditional call be composed with another type of call. For example, a program loop may conditionally call another module within the loop's body. How should this be represented in the OD? Certainly the call is a conditional one and may be represented using the conditional module call construct. However, the module is being called repetitively within a loop, so it may just as well be represented using the iterative call construct. Another possibility is to represent the call using a composition of the two representations, indicating that the module is called both iteratively and conditionally. The problem is that this raises ambiguity in that the diagram does not indicate whether the call was made conditionally in the body of a loop, or whether it was made iteratively as the consequence of some condition being true. This ambiguity must be resolved if the iterative and module call representations are to be used properly in the OD.

**Package Specifications.** A package may be recognized from a parse of an Ada program, and the operations contained within the package may be recognized just as easily. The direction of the parameters may also be determined syntactically through the presence of the *in*, *out*, and *in out* parameter designators. However, the distinction of parameters as either control or data parameters may not be recognized as easily. In fact, it is possible for parameters to be used as both control and data parameters, so the automated classification of an operations's parameters as control or data may not be feasible. Finally, the detection of exceptions may be determined easily through syntactic analysis. Current work has focused on generation of the Booch version of the Ada package symbol [BOO83].
Generic Packages. The specification of a generic package may be recognized easily from a parse of an Ada program, and the generic parameters which must be specified in an instantiation of the package, the operations provided by the package, the parameters to the operations and their direction may also be recognized syntactically. However, the generic package suffers from the same problem as the package in the area of detection of control and data parameters. Again, the automated classification of parameters as either control or data parameters may not be feasible.

Tasks. The declaration of a task may be recognized syntactically in a parse of an Ada program. Much of the desired information needed in the creation of an OD representation of a task may also be obtained from syntactic analysis, such as the entries provided by the task, the parameters and their associated directions for each of the task entries, and any guards placed on the task entries. However, there are two items in the OOSD depiction of a task that may not be obtainable in an automated fashion during reverse engineering. The first of these is the omnipresent problem of distinguishing between control and data parameters which has already been discussed in previous paragraphs. The second is the placement of sequencing numbers on the task entries. Only in the most trivial cases may these numbers be properly derived. In more complex cases, the sequencing numbers would be meaningless or even misleading, and the OD would probably be better off by omitting these numbers.

Generic Tasks. The depiction of a generic task in the OD suffers from many of the same problems as the depiction of a task, and the reader is referred to the previous paragraphs for a discussion of these problems. Other than that, the detection and representation of a generic task should provide no further problems.

**Instantiation of Generic Packages.** The instantiation of a generic package in an Ada program may easily be determined syntactically. The generation of a proper OOSD symbol for generic package instantiation will require actual parameters to be matched with formal parameters. Otherwise, it should pose no difficulty.

**Visibility.** The depiction of the semantic visibility of a package to a module in an Ada program may be determined syntactically, but the representation may prove to be misleading. There are two "varieties" of visibility that must be represented: packages lexically included in the declarative section of the current compilation unit and packages included via the **with** clause, which are separate compilation units. For example, a package in an Ada program may only be visible to a small section of a module (for example, a block in a module containing a loop may declare the package in the declaration area and call a function in the package iteratively during the loop. The package would therefore be visible throughout the scope of the block, but would not be visible in the statements preceding and following the block. Therefore, the depiction of the package as being visible to the module could be misleading to the user unfamiliar with the underlying code. Although generating the representation is not difficult, the sensibility of utilizing the representation must be considered. When visibility is determined by the **with** clause, a separate icon is, of course, necessary and appropriate.

**6.2 Symbol Interconnections and Diagram Layout**

The actual automatic layout of the generated object diagram with respect to symbols and interconnections is the most formidable problem that must be solved. Whereas the CSD has a flexible but well-defined physical layout, the OD layout is not well-defined. In fact, the CASE tools that support the OOSD notation require the users to "manually" arrange the
symbols. Determining the feasibility of an algorithmic and/or heuristic solution which yields a reasonably comprehensible diagram layout is a complex topic which warrants further investigation.

The majority of approaches to the automated layout of a directed graph have focused on minimizing the number of crossovers among the flow lines in the graph. Warfield [WAR77] detailed an algorithm that proposed the reordering of a directed graph into a number of vertex subsets (called levels) and the minimization of the number of crossovers between subsequent levels using a special table called a generating matrix. The major drawback to the approach is that the generating matrix technique is only applicable to cases in which there are five or less vertices in each level. Warfield realized this, and went on to propose a number of techniques for graph manipulation that he believed could prove useful in the development of improved graph layout algorithms.

Sugiyama [SUG81] developed a heuristic algorithm for crossover minimization called the penalty minimization (PM) method that could be integrated with Warfield's algorithm for application to graphs with more than five vertices in a level. Since the penalty minimization method is combinatorial in nature, Sugiyama also developed a heuristic algorithm called the barycentric (BC) method that would make the PM method practical. In addition to this improved algorithm for minimizing the number of crossovers between successive levels of a graph, Sugiyama also developed the priority (PR) layout method for improving the horizontal positioning of the vertices in a level.

Paulisch [PAU90] noted that two major problems with Sugiyama's work were that the algorithm did not allow the user to specify preferences and constraints on the diagram layout, and that the algorithm did not take previous layouts into account when updating a graph and could produce wildly different layouts from minor perturbations of the graph, leading to graph
layout instability. She theorized that both problems could be solved by incorporating a layout constraint manager with Sugiyama’s algorithm and developed a method for doing so. Her approach involved adding a constraint manager for each dimension of the graph (x, y, and z) and providing a set of constraints for each dimension form which the user could choose a subset to be applied to the graph. The constraint manager would reconcile the various constraints provided in this manner by the user with the constraints imposed by the application and the layout algorithm to produce a graph layout. The implementation chosen by Paulisch used a binary search among constraints in the reconciliation process, a method that provides a quick response time but does not necessarily yield an optimal solution. A better approach might lie with the use of genetic algorithms to "breed" an optimal graph layout solution. The feasibility of this approach, coupled with the use of the Warfield/Sugiyama/Paulisch algorithms, is presently being investigated by members of the GRASP/Ada research project.

6.3 GRASP/Ada ODgen Processing Alternatives

In the development of the ODgen design specification, three distinct development methods were considered. The major difference among these methods is linked to the degree of involvement of other commercially available tools and the ability of the user to specify these tools. The first method considered was to create ODgen as a stand-alone system. A second alternative was to use GRASP/Ada as a driver for a set of subprogram invocations which would use VADS, ODgen, and StP/ADE in sequence to produce the architectural diagrams. Finally, the third alternative considered was to use GRASP/Ada as a shell from which the user could invoke each of the three tools at his convenience. In this section, these
three methods are examined in more detail, and the advantages and disadvantages associated with each method are outlined.

**ODgen Is Independent of Commercial Tools.** This method would involve the development of a stand-alone architectural diagram generator. The generator would not be dependent on commercial tools such as VADS and StP/ADE. Instead, the parser/scanner developed in Phases I and II of the GRASP/Ada research project would be extended to extract the information needed for the representation of architectural diagrams. A method for specifying or identifying the complete set of files comprising the Ada system would have to be developed (this may require some involvement from the user). The major advantage of this method is that the tool would not be subject to the whims of the manufacturers of commercial tools (i.e., the tool would not be rendered useless if VADS were to become unsupported, if the DIANA representation were subjected to large-scale change, if the StP/ADE file formats and representation methods were to be changed, etc.). On the other hand, this method would involve substantially longer development time, as a tool for identifying the dependencies among a set of Ada source files would have to be developed. In addition, a tool for viewing and printing the architectural diagrams would need to be developed. Because a substantial amount of effort has already been spent in the development of the GRASP/Ada X11R4 interface, extending this interface to display the architectural diagrams could benefit from the groundwork already laid in Phases I and II. The major goals which would need to be accomplished are the development of X11R4 widgets for the representation of each of the OOSD symbols, and the development of layout heuristics and modified layout widgets suitable for displaying the OOSD symbols.

**ODgen Invokes VADS and StP/ADE.** In this method, the ODgen component of GRASP/Ada would first invoke VADS to generate a DIANA net for the specified set of Ada
source files. ODgen would then traverse this net to obtain the required information and generate an internal representation for the architectural diagrams. This information would then be shaped into a format suitable for StP/ADE and saved. Finally, StP/ADE would be invoked to view the architectural diagram. All of this would be transparent to the user: after specifying the Ada source files and a number of ODgen options, GRASP/Ada would invoke the tools in sequence and bring up StP/ADE as a subprocess displaying the generated diagrams. The major advantage in this approach is that it would utilize already-existing tools to speed the development effort. Instead of writing yet another Ada parser, intermediate representation generator and OOSD diagram display, the research effort could concentrate on the task of obtaining architectural details and composing meaningful architectural diagrams from them. However, relying on commercial tools could be dangerous as subtle changes in the formats of either the VADS representation or the StP/ADE representation could require major, sweeping changes in the ODgen system. In addition, the use of commercial tools could greatly limit the number of potential users for the ODgen system. Instead of only needing the ODgen system, the user would also need the VADS Ada compiler and the StP/ADE software development system - two costly components. For many university research installations, the costs of these systems would be prohibitive and would virtually eliminate the potential use of ODgen.

**GRASP Runs Independently of VADS and StP/ADE.** The user invokes VADS to create DIANA nets, invokes GRASP to generate CSDs and ODs, and invokes StP/ADE to view the ODs. In this scenario, the GRASP/Ada interface would be partially customizable by the user. Instead of relying on a specific Ada intermediate representation generator and OOSD diagram display, the user would be able to select from a limited number of commercial tools. To accomplish this, a minimal ODgen interface for each tool would be
identified and a suitable data representation would be specified. ODgen would then be designed to transform the input Ada source data into an architectural diagram representation in the output format. Then, customizing GRASP/Ada for new intermediate Ada representations and OOSD diagram formats would consist of simply writing a filter transforming the data from one representation to another. For example, customizing GRASP/Ada to work with the VADS DIANA representation would require a filter to be written to traverse the DIANA nets and store the needed architectural information into a file in ODgen’s input format. Similarly, customizing GRASP/Ada to work with the StP/ADE tool would require a filter to be written translating the ODgen output format into StP/ADE’s input format. This method would allow GRASP/Ada to be fairly portable without depending on strict reliance on commercially available tools. On the other hand, this method would require an extensive and easily translatable interface format to be developed for both ODgen’s input and output formats. Finally, the amount of effort required for the writing of filters for new representations could be potentially quite large, depending on the format and accessibility of the new representations.

6.4 Displaying the OD - Screen and Printer

Generating visual displays of the object diagrams will require display methods to be generated for the screen and printer. Since the GRASP/Ada interface for Phases I and II was developed using the X Window System (a portable graphical environment gaining widespread acceptance) and numerous utilities have been developed in the creation of that interface, the development of a display mechanism for the object diagrams in X11R4 would be a logical extension to the previous work. In addition, the PostScript page description language was used in Phases I and II for the hardcopy output of the CSD diagrams. Because PostScript
is a nearly universal output description language for laser printers, the development of PostScript utilities for printing GRASP/Ada object diagrams would ensure the portability of GRASP/Ada. In this section, some of the issues and considerations involved in the generation of visual displays for the object diagrams for the screen and printer are discussed.

Screen representations. In the X11R4 system, objects on a screen are often represented using widgets (a user interface component embodying a single concept: e.g., buttons, labels, scrollbars, etc.). The development of the interface for Phases I and II of the GRASP/Ada research project was implemented using the X11R4 Athena widgets, a general purpose widget set shipped with the X11R4 system. Numerous utilities were developed by the GRASP/Ada implementation team to simplify the use of these widgets to providing facilities for browsing files, generating alert boxes and dialogues, creating text editor windows, and specifying menus. These utilities would be invaluable in the development of the ODgen interface, but additional utilities will be needed. In particular, there are no suitable widgets in the Athena set for displaying the various OOSD symbols. A reasonable approach to implementing a display mechanism for the ODgen diagrams would involve the creation of a set of widgets, one for each of the symbols in the OOSD set. These widgets could be subclassed from existing widgets in the X11R4 Athena set, minimizing the amount of effort required to create them (although this would cause them to need revision with subsequent releases of X11). And once written, these widgets could be used in other CASE programs written for X11R4. Next, constraint and layout widgets would need to be designed to facilitate the layout of these OOSD symbols. Again, a suitable widget could be created by subclassing an appropriate Athena widget, in this case, probably the Form widget. Such a widget would be responsible for laying out an architectural diagram and redrawing it after
modifications, thus justifying the need for embedded logic to be written for the automatic layout of the ODgen diagrams.

**Printer Representations.** In Phases I and II of the GRASP/Ada research project, three different types of output devices were utilized. The first was the LN03 printer, a printer manufactured by DEC with the capability of printing sixel graphics. Printing the CSD on the LN03 printer was accomplished by generating sixel representations for each of the CSD characters and then printing each CSD character as a small graphic image. The text of the Ada source program was printed normally using the LN03 resident fonts. This method had several major disadvantages: it was not portable (sixel graphics are a proprietary format of DEC), it was slow (printing each CSD character as a graphic bitmap was a time-consuming process), it was crude (the sixel graphics format did not allow for a high degree of resolution and the generated CSD characters suffered from jagged outlines), and it wasted file space (the space required to store the sixel representation of a single CSD character was equivalent to the space needed to store over 200 text characters). The second output device utilized was the HP LaserJet II printer, an extremely popular laser printer. Using the LaserJet II enabled the GRASP/Ada program to utilize a specially prepared CSD font that could be downloaded to the printer. This method allowed the CSD to enjoy greatly improved resolution over the LN03 characters, a much smaller file representation (since each CSD character could now be represented as a single extended ASCII character rather than a large bitmap image), and faster printing speeds. However, this method was still tied to a single commercial printer, the HP LaserJet II. The third method allowed the GRASP/Ada program to generate CSDs that could be printed on a wide variety of printers by generating CSDs using the PostScript page description language. PostScript representations for each of the CSD characters were generated using a series of PostScript graphic primitives to describe how to draw each
character. Once designed, these characters were merged with a PostScript program that uses the Adobe Courier font to produce a modified Courier font containing the CSD characters. The CSD font can be installed on any PostScript printer by downloading this PostScript program. Thereafter, CSDs can be printed by sending them to the printer and specifying this specially modified Courier font. The advantages to this method are many: the CSD can be printed on any printer (laser, inkjet, dot-matrix, etc.) that supports PostScript; the CSD can be printed at the highest resolution the printer is capable of producing, which generally produces results of outstanding high quality on most laser printers; and the CSD font can be scaled to any size, allowing the CSD to be printed at any size the user wishes (unlike the previous methods, which allowed the user to have only one font size). For Phase III of the GRASP/Ada research project, a library of PostScript routines for printing each of the OOSD symbols must be created. The ODgen program can then invoke these routines to create a sequence of descriptions for printing the OOSD diagram to any PostScript printer. Care must be exercised in the creation of these routines to ensure that they match the appearance of the X11R4 widgets also corresponding to these OOSD symbols. Like the modified X11R4 widgets for the OOSD symbols, these PostScript routines should also be portable to any other CASE tool for the X11R4 system.

6.5 Incremental Changes to the OD

The ultimate goal of the ODgen phase of the GRASP/Ada research project is to allow the user to reverse engineer a set of Ada source files into an architectural diagram. For a large system, this may take some time. It would be desirable to have the user do the reverse engineering once and then have ODgen incrementally change the OD as the user makes
changes to the source code. However, this is an extremely complex issue, and some of the problems involved in doing this are addressed in this section.

The first problem involved in the incremental updating of the OD is that if the DIANA notation is used to obtain the syntactic and semantic information from the Ada source files for the generation of the OD, then we are immediately stymied. In its current states, DIANA does not support incremental updates. If a portion of a file is changed, then the entire file must be recompiled to update the DIANA net. Thus, any implementation of ODgen which relies on a DIANA net for its information could not support incremental diagram updating. A parser specifically modified for incremental updates could prove useful in generating the diagrams, but such parsers are extremely complex to design and are often excruciatingly slow in practice. Teitelbaum and others [TEI81] have outlined some of the problems involved in incremental parsing in their work on the development of syntax-directed editors.

The second problem involved in the incremental updating of the OD lies in the unrestrained freedom of editing by the user. The proper generation of an OD relies on the existence of a relatively complete Ada compilation unit, where "relatively complete" is defined as a main (or "driver ") program along with at least the specifications of the packages, tasks, and modules upon which it depends. The existence of a relatively complete program is not normally a problem in reverse engineering, where the user has a system and is just trying to decipher its function and meaning. However, the user could initiate what, to him, appear to be very minor changes that could lead to many changes throughout the ODs and CSDs. As an example, imagine that the user renames a small package. To him, this may be a minor modification, but it would create havoc for the ODgen system. The system would no longer be relatively complete, as it would now contain what would appear to be a
new and unreferenced package along with a large number of package inclusions that may no longer be satisfied. This and related problems must be addressed in any attempt at providing incremental updates to the ODs and CSDs.

6.6 Internal Representation of the OD - Alternatives

Although the DIANA intermediate representation for Ada may be used to gather information for the creation of the OD, and the StP/ADE format may be used as one possible output representation for the OD, a more extensive and comprehensive internal representation tailored for the needs of the OD generator is desired. Several alternatives are presently under consideration for this internal representation of the OD. These alternatives include (1) storing the OD as a single ASCII file, (2) storing the OD as a number of files tailored to the internal data structures utilized by ODgen, and (3) completely bypassing the internal representation to directly generate the OD from a DIANA net. Each of these approaches has its own merits with respect to processing and storage efficiency, and these qualities are in this section.

Single ASCII File. The most direct approach is to utilize the StP file format. This would present the option of viewing the OD via the StP/ADE system. However, although the StP file format is "open architecture," it is a proprietary format and is, therefore, subject to change. Because the function of the ODgen system will be dependent to a high degree on the organization of the data upon which it operates, a stable data format is desired. Therefore, an original data format might prove to be more useful over time as it would reduce the problems of compatibility with commercial formats (filters could be written to translate from the ODgen format to other formats). In addition, commercial formats such as the StP format might lack provision for all of the information which might be needed for the OD. This is particularly true for the case in which the user may wish to link CSDs generated using
the GRASP/Ada CSD generator to objects in the OD. A comprehensive internal representation consisting of segments storing information for each of the OOSD symbols may prove to be necessary to fulfill all of the needs of Phase III of the GRASP/Ada research project.

**Multiple ASCII Files.** Because a typical Ada program will involve a number of source files, an alternative to storing the data relating to a system in a single file is to store the data in a number of files, each linked to one or a number of source files. Such a system would decompose the intermediate representation into a number of smaller units. With an appropriate indexing scheme, this could bring about increased performance in the ODgen program as the system would not have to peruse unnecessary information to get to the data it needs. This scheme might also prove helpful in producing incremental changes to the OD. The major drawbacks to this method are the greatly increased number of files generated and the overhead involved in the indexing scheme.

**Direct Generation From DIANA Net.** If tight coupling and integration with a commercial Ada development system such as VerdiX VADS is desired, then direct generation of the OD from the DIANA net produced as a result of compilation could be performed. This would require a layer of software which traverses the DIANA net and calls the appropriate OD primitives as unit nodes are encountered. This approach would apparently eliminate the possibility of directly editing the OD since the DIANA interface does not support modifying the net, only reading it.

6.7 Navigation Through Large ODs - **Alternatives**

Because many Ada software systems are fairly large in size and scope, some facility for easily navigating the ODs generated for them must be provided. There are three
navigational methods presently being considered for use in the ODgen system. These include (1) the creation of a "table of contents" for the system, (2) the direct navigation throughout the system using a "point and click" interface similar to that provided in hypertext or in the HyperCard application on the Apple Macintosh, and (3) a combination of these two methods. In this section, these methods are described and the relative advantages and disadvantages pertaining to each method are presented.

**Index (or Table of Contents).** An index, similar to that presented in the Xman application provided with the X Window System, would be used to navigate among a system of CSDs and ODs. After generating the CSDs and ODs, the user would be presented with an ordered list of the diagrams. To view a diagram, the user would click on the index entry and the corresponding CSD or OD would be displayed. The index entries would be created as the respective diagrams are generated and stored in the GRASP/Ada library (see Section 6 below). The greatest advantage to this method is that the user may see the entire range of diagrams at once - nothing is hidden. However, for a nontrivial system this may be a list of daunting proportions requiring the user to have some familiarity with the system to be of any use. This disadvantage may be offset by layering the index so that only top level diagrams are presented at first, each containing links to a sublist of associated diagrams, etc. In addition, icons or informative labels could be attached to each index entry to provide the user with additional information regarding the diagram under consideration.

**Direct Navigation Via ODs.** With this method, after generating the CSDs and ODs for an Ada system, the user would be presented with the top level diagram for the system. The user could reach other diagrams in the system by clicking on the OOSD symbols in the top level diagram: this would bring up the associated subdiagram or CSD on the screen. The user is allowed to click on procedure, function, and task entry calls in the OD directly and
a separate OD window is opened containing the selected OD or fragment thereof (there may be a problem using/implementing this approach since the mouse is also used for editing). Browsing the OD in this manner would be much like working with hypertext, and would provide some of the advantages and disadvantages associated with hypertext. For example, the user may gain an incomplete view of the system by following odd threads throughout it. The user may also have to sift through a great deal of high level detail to get to low level components. This might prove frustrating in practice. However, the user would have the freedom of navigating throughout the system in an logical manner.

**Combination of Index and Direct Navigation.** The two approaches discussed above both have their relative merits and problems. A more desirable solution to the navigation of large ODs possibly lies in the combination of these methods. By providing a linked series of ODs and CSDs with a comprehensive listing of all diagrams, the user would have unrestrained freedom in navigating throughout the system. Additional utility could be provided by allowing the user to "mark" viewed and unviewed diagrams in the index, and by maintaining a list of recently visited diagrams. However, this approach would be more difficult to implement and would take careful analysis and design to be effective.

6.8 Exploding/Imploding the OD

The OD window should provide the user with the capability to explode or implode the OD based on Ada constructs and complete diagram entities (e.g., procedures, functions, tasks and packages). This capability directly combines the ideas of chunking with the major threads of control flow which are major aids to comprehension of software. The OD can be supplemented by *architectural CSD* (ArchCSD) [DAV90], a diagram produced by collapsing
the CSD based on procedure, function, and task entry calls, and the control constructs that
directly affect these calls.

6.9 Generating a Set of ODs

Since GRASP/Ada is to be used to process and analyze large existing Ada software
systems consisting of perhaps hundreds of files, an option to generate all the CSDs at once
is required. Generating a set of ODs should be facilitated by entering a wildcard file name
(e.g., *.*). An OD generation summary window should display the progress of the
generation by listing each file as it is being processed and any resulting error messages. The
summary should conclude with number of files processed and the number of errors
encountered. The default for each OD file name is the source file name with .od appended.
Generating a set of ODs can also be considered a user interface requirement rather than
strictly a OD generator requirement.

6.10 Printing An Entire Set of ODs

Printing an entire set of ODs in an organized and efficient manner is an important
capability when considering the typically large size of Ada software systems. A book format
is under consideration which would include a table of contents and/or index. In the event
GRASP/Ada is integrated with IDE/StP/ADE, the StP Document Preparation System could
possibly be utilized for this function.

6.11 Relating the CSD and OD - Alternatives

For each OD in the system under scrutiny, the user will have the ability to click the
mouse on any OOSD symbol in the diagram and be presented with the underlying CSD or a subsequent level of OD, if it exists. In addition, a button will be provided on each OD or CSD window allowing the user to step back up one level in the diagram hierarchy to see the "parent" diagram. In this manner, the user will be able to fully traverse the ODs and CSDs comprising the system using a "point and click" approach. In addition, the user may choose to bypass the hierarchical traversal by simply choosing the diagram to be viewed from the index list of diagrams.

Each CSD corresponds to an object symbol (e.g., procedure, function, package, task, task entry). These may be nested and may each have an interface and a body. Conceptually, the CSD may be collapsed to a graphic symbol. A group or system of these symbols could be interconnected (logical inclusion and/or invocation) to form an object diagram. This could be thought of as "growing" or synthesizing the system diagram. The user would be able to open any of these symbols to see the lower level diagram associated with it.

If the StP/ADE system is to be used for viewing the ODs and CSDs, the ODs could be viewed directly. The CSD could be displayed as an annotation in StP/ADE. This would require that the CSD font be downloaded into the appropriate StP/ADE window for the diagram to be viewed properly.

6.12 Index and Table of Contents Relating the CSDs and ODs

An index of all CSDs and ODs should be available via the GRASP library. The index should be presented in a window to the user, and upon the selection of an index entry, an appropriate CSD window should be opened. The index will provide an additional means of navigation among diagrams in an interactive mode, and it will be the basis for printing a
complete set of all diagrams. See the section below entitled, "The GRASP Library" for more information.

6.13 Design and Implementation of Preliminary ODgen Prototype

The overall organization and composition of the prototype system is discussed first, with special attention paid to the design of the ODgen widget set. This is followed by a description of the use of a subset of the proposed GRASP library in the development of the prototype. Finally, an informal specification of the organization of the X11R4 user interface that allows the ODgen prototype to function as a standalone tool is given, along with a summary of the changes that must be made to integrate the final ODgen system with the GRASP/Ada system.

Overview. The primary purpose of the ODgen object diagram generator prototype was to assess the feasibility of recognizing and extracting design information from Ada source code. Mappings were assigned between the target diagrams, described above, and the appropriate Ada constructs. An X11R4 widget set, with one widget for each of the proposed ODgen diagram elements, was designed, and the Package widget was implemented. Next, a subset of the GRASP library which would enable the storage and manipulation of structural information was created. Finally, an X11R4 user interface based on the freely available Athena widget set was developed which would allow ODgen to be used as a standalone tool that would work independently of the GRASP/Ada system. Figure 13 shows a typical window presented to the user by the preliminary prototype of ODgen. ODgen uses a simple X11R4 user interface that provides a menu bar and three paneled areas. The menus allow the user to choose an Ada file, load the file, generate an object diagram, display an object diagram, save the object diagram, change the size of the font, and exit the program. The first

paned area is used by ODgen to report errors and to display information pertaining to the program's status. The second paned area is used to display the source code or CSD for the Ada program of interest, and the third paned area is used to display the corresponding object diagram. Each of the paned areas may be sized by the user, so that an all-source view may be obtained as in Figure 14. The user may equally choose to see an all-diagram view as in Figure 15, or a multiple view as in Figure 16.

**General Development Approach.** The overall organization of ODgen may be seen in Figure 17. To initiate the implementation of ODgen, a lexical description of Ada was obtained and used as an input for the lexical analyzer generator LEX to create a scanner for Ada systems. The lexical description was enhanced with a number of customized routines which would enable the filtering of CSD characters as well as assist in the capture of data relating to the source code (such as line numbers). Next, an Ada grammar was obtained and instrumented with a number of action routines which would extract structural information during a parse of Ada source code and preserve this information in memory using a prototype of the GRASP library. The resulting Ada grammar was too large for the parser generator tool YACC to handle, so the widely available YACC-workalike BISON (a parser generator upwardly compatible with YACC that accepts larger grammars) was used to generate an Ada parser. This parser and the previously generated scanner were tested on a number of programs provided by NASA and Boeing to ensure that they would indeed parse legitimate Ada programs. (A special note: due to the syntactic structure of Ada, many Ada grammars introduce slight modifications to several of the productions in order to simplify the creation of the parser. The grammar utilized by GRASP is one of these, and therefore ODgen will parse some syntactic constructs that are not legitimate Ada. These deviations are few, however, and are not likely to occur in practice. In addition, one of the underlying

Figure 17. ODgen Development Approach
assumptions made at the onset of the GRASP project was that the input programs would be syntactically correct.)

**ODgen Widget Set.** The next step in the development of ODgen was the design of the widget set for the display of the object diagrams. Widgets were designed for each of the object diagram symbols, including: packages, tasks, generic packages, generic tasks, and subprograms. The Package widget has been implemented in the prototype. Several practical concerns severely influenced the design of the widgets. In the following paragraphs, these concerns are discussed along with their impact on the development of the widget set.

Initially, the ODgen widgets were to be developed as compound widgets similar to the X11R4 Athena Dialog widget. The X11R4 Athena Form widget would have been used as a background upon which to place the ODgen symbol labels (represented with the X11R4 Label widget). The objects and modules of the Package widget and the entries of the Task widget could have been neatly represented using the X11R4 Athena Command widgets, or derived subclasses. These compound widgets could therefore have been developed fairly quickly using reliable off-the-shelf components. However, this approach was abandoned for several reasons. First, this widget set was developed in May of 1991 under X11R4. Release 5 of the X Window System was slated for distribution in the fall of 1991. Between releases 3 and 4 of the X Window System, major changes were made in the implementation of the Athena widget set, with the developer freely admitting that he had given up on maintaining compatibility for any widgets subclassed off of the Release 3 widgets. Therefore, the decision was made to rely as little as possible on the Release 4 widgets in case a similar fate should await the Release 5 widgets. Second, to present the objects as rounded rectangles, the widget set would have to make use of the XmuShapeRoundedRectangle shape extension. Because not all X servers support this extension, its use was prohibited to maximize
portability. Third, the Athena Command widget, being a full widget, carries a great deal of unnecessary overhead which is unnecessary and unwanted in this application. As a typical application using the Package widget would contain a great many objects and modules, a better implementation would operate similarly to the Athena SimpleMenu widget, using gadgets rather than widgets to represent the objects and modules.

The second possibility considered was to implement the Odgen widget set as a series of simple composite widgets and to provide gadgets for the objects and modules of the Package widget and for the entries of the Task widget. This approach would have the added advantage of allowing the programmer to subclass these gadgets and therefore easily customize the widget’s appearance. However, this approach was abandoned for several reasons. First, this would have forced the Package and Task widgets to be implemented as a number of widgets (the Package or Task widget itself and the associated gadgets), substantially increasing its complexity and comprehensibility to the applications programmer. This approach was undesirable since a major goal in the development of this widget was its ease of use. Second, composite widgets are widely regarded as being difficult to write as they must deal with geometry management and other concerns. In addition, they incur more overhead than simpler classes of widget, and this overhead was regarded as being unnecessary in this instance. Third, because the objects are represented using rounded rectangles, and because gadgets draw directly into their parent’s window, this approach would have required a programming workaround because of an extremely subtle problem which will not be discussed here. Fourth, Release 5 of the X Window System is rumored to have made several changes in the way in which gadgets and objects are implemented. To prevent substantial rewriting of this widget in the near future, and for the other reasons cited above, this approach to the implementation of the ODgen widget set was not taken.
The third possibility considered, and the one which was actually used, was the implementation of the Package and Task widgets as simple widgets with convenience functions for manipulating the objects and modules and entries. This approach had several advantages, chiefly the simplified programmer interface. The applications programmer would only have to deal with one widget, rather than with a composite widget and a number of gadgets and all of their associated header files and resources. A second advantage is that using convenience functions to manipulate the subcomponents sufficiently abstracts the process such that the widgets could be rewritten in a future release to support gadgets, after the Release 5 gadget modifications are known, without requiring application programs to be modified (the convenience functions could be modified to create instances of the gadgets and insert them into the appropriate widget, therefore achieving backward compatibility). A third advantage is that implementing the ODgen widget set as a subclass of only the Athena Core widget greatly minimizes the widget overhead which would accompany a compound or composite widget.

However, there are several disadvantages to the chosen implementation approach. Because each ODgen component is represented by only one widget, associating translations to actions operating on the subcomponents becomes difficult. To offset this, a routine was written which fakes events for the subcomponents (actually, this routine was lifted from the X11R4 Athena SimpleMenu widget and modified). A default translation is provided which works reliably and will probably satisfy most application programmers, but other translations using the provided actions are possible provided the application programmer remember that the subcomponents do not truly receive events.

In summary, the current implementation of the GRASP/Ada Package widget is a product substantially influenced by the current release status of the X Window System, the
impending changes in the next release of X, the history of sweeping changes in the past releases of the Athena widget set, and the GRASP/Ada goals of providing an easy-to-use tool that will require little future maintenance.

**GRASP Library.** The next step in the development of the ODgen prototype was the design of a subset of the GRASP library. This subset needed to be suitably complex to store and manipulate structural information pertaining to the Ada program under study, yet simple enough to implement in a variety of ways, enabling the feasibility and performance of the library to be evaluated. Action routines were embedded in the Ada grammar to extract information for each package, task, complex data type, generic unit, task entry, and procedure call. This information was combined with other data (source file name, beginning line number, ending line number, identifier, scope) and stored in the GRASP library prototype for retrieval and use by the ODgen object diagram display mechanism. This prototype is currently under evaluation to determine whether this approach will be chosen or abandoned in favor of one of the two alternatives: the use of the VADS library system with DIANA; or the use of the StP TROLL/USE relational database system.

**ODgen User Interface.** The next part of the development of the ODgen prototype was the design of a user interface that would enable ODgen to be used as a standalone system. The goals of this part of the development were twofold: first, to design a functionally complete interface that would enable the user to easily use ODgen as a standalone tool; and second, to design an interface sufficiently compatible with the GRASP/Ada CSDgen component and user interface such that the two could be easily merged.

To meet the first goal, the user interface tools created in the development of the CSDgen component were streamlined and slightly modified to be applicable to both
interfaces. The tools were soundly designed and required very little modification for their use in the ODgen prototype. To meet the second goal, the "look and feel" of the CSDgen component was preserved in the design of the ODgen interface, with a few improvements. The multiple windows characteristic of the CSDgen component were reduced in number with the introduction of paned windows, thus slashing the amount of overhead associated with the implementation of multiple windows, as well as more tightly associating the object diagrams with their associated code, and increasing the freedom of the user in determining the customization of the various views.

The parser, scanner, customized widget set, GRASP/Ada interface utilities from the development of CSDgen, and a customized driver program were combined to create the ODgen executable. This program allows the user to select and load either Ada source files or CSD files into a window and to generate the corresponding object diagram. The program is currently under evaluation to determine any future enhancements which may prove useful. When the evaluation is complete and the standalone program is deemed ready for distribution, it will be integrated with the CSDgen component to complete the GRASP/Ada system. The major problem which is foreseen in the integration is the combination of the two sets of action routines into one, a task which will be greatly simplified due to the GRASP utility routines common to each.
7.0 Future Requirements

The GRASP/Ada project has provided a strong foundation for the automatic generation of graphical representations from existing Ada software. To move these results in the direction of visualizations to facilitate the processes of verification and validation (V & V), numerous additional capabilities must be explored and developed. The proposed follow-on research is described by tasks partitioned into three phases. A small team is expected to work on each phase for a period of up to one year. Operational prototypes will be demonstrated at the end of each phase.

7.1 Phase 1 - Generators and Editors for Visualizations

Phase 1 consists of five subtasks. The first is to formulate a set of graphical representations that directly support V & V of Ada software at the algorithmic, architectural and system levels of abstraction. This task will include an on-going investigation of visualizations reported in the literature as currently in use or in the experimental stages of research and development. In particular, specific applications of visualizations to support V & V procedures will be investigated and classified. A small, but representative, Ada program will be utilized to formulate and evaluate a set of graphical representations, and the feasibility of reverse engineering the diagrams from Ada PDL and source code will be evaluated. These graphical representations are expected to undergo continual refinement as the automated tools that support them are developed.

The second subtask of Phase 1 is to design and implement a prototype software tool to generate visualizations from various levels of Ada PDL to support V & V during
detailed design. The previous efforts of the GRASP/Ada project have focused on the
generation of graphical representations from syntactically correct Ada source code. Since
most detailed design is done in an Ada PDL which is less rigorous than Ada, the capability
to generate visualizations directly from PDL is required to facilitate verification during the
detailed design phase of the life cycle. The diagrams generated in Phase 1 are expected to
focus on the algorithmic level of representation.

The third subtask of Phase 1 is to design and implement a prototype software tool
to generate visualizations from software written in C. Since much of NASA's production
software is currently being written in a combination of C and Ada, the capability to generate
visualizations from C source code is required to support visual verification of the integrated
software system. And since C is intrinsically less readable than Ada, maintenance personnel
may greatly benefit from algorithmic-level diagrams generated from C source code.

The fourth subtask of Phase 1 is to design and implement a prototype graphically-
oriented editor which provides capabilities for dynamic reconstruction of the diagrams
generated in the tools described above. This capability will directly support visual
verification at its most primitive and important levels, as PDL or source code is entered or
modified. In this mode, the graphical representation can provide immediate visual feedback
to the user in an incremental fashion as individual structural and control constructs are
completed. The present GRASP/Ada prototype generates the graphical representation only
after a complete compilation unit of source code has been entered correctly.

Finally, the fifth subtask of Phase 1 is to design and implement a user interface
capable of supporting a state-of-art multi-windowing paradigm. The user interface for
the tools developed in this research project will be built using the X Window System. This
should facilitate eventual integration of the tools into any Ada programming support
environment (APSE) which runs under a similar window manager. In addition, this multi-windowing paradigm will allow the toolset to take full advantage of the current capabilities of powerful workstation hardware.

7.2 Phase 2 - Evaluation and Extension

Phase 2 consists of five subtasks. The first is to continue the tasks defined in Phase 1 with respect to refinement of the V & V process, implementation of the prototype tools, and intertool communication. The results of the investigation in Phase 1 will be used to refine the V & V process and the visualizations which support the process. The individual tools prototyped in Phase 1 will be integrated through a window manager for the X Window System. The user interface and a persistent storage mechanism such as DIANA will provide the basis for intertool communication.

The second subtask of Phase 2 is to evaluate the individual tools developed in Phase 1. Representative sets of programs written in PDL, Ada and C will be utilized to evaluate the set of graphical representations generated by the prototype. These graphical representations and the automated tools that support them are expected to undergo continual refinement during Phase 2.

The third subtask of Phase 2 is to design and implement a prototype software tool for generating architectural diagrams (ADs) from Ada PDL and a combination of Ada and C source code, to support the process of V & V. The Phase 1 prototype, which focused on the generation of an algorithmic notation, will be extended to include architectural diagrams. This task will include (1) development of procedures for identifying and recording module interconnections, (2) development of algorithms for architectural diagram layout, and (3) development of methods for displaying/printing architectural diagrams on hardware.
available for this research. The tool will be used on representative Ada software. The generated set of graphical representations will be evaluated for completeness, correctness, and general utility as an approach to reverse engineering.

The fourth subtask of Phase 2 is to investigate the potential for integration of the toolset with currently available commercial systems. Commercial CASE systems and APSEs will be surveyed to determine appropriate commercial systems to target for integration. Many vendors are currently developing "open architecture" systems to facilitate the integration of third party tools.

The fifth subtask of Phase 2 is to investigate the use of visualization tools to support software testing, particularly unit level branch coverage analysis. Software testing is an important and essential component of V & V. Visualization tools are extremely useful for analyzing and reporting branch coverage. In addition, they may be very useful for graphically selecting a path for which data items to drive the path should be generated. This task would be done in conjunction with QUEST/Ada, a related project which has focused on the theoretical issues of test data generation [BRO90].

7.3 Phase 3 - Evaluation and Integration with Commercial Systems

Phase 3 has three subtasks. The first is to complete the tasks defined in Phases 1 and 2 with respect to refinement, intertool communication, and integration of an operational prototype. In particular, the user interface will be completed as a basis for overall integration of the prototype tools.

The second subtask of Phase 3 is to evaluate the toolset developed in Phases 1 and 2. Software systems which are representative of three levels of size and complexity, will be utilized to evaluate the set of graphical representations generated by the prototype as well as
the prototype itself. These systems will be written in Ada/PDL, Ada, C, or a combination of Ada and C. The graphical representations generated and the prototype are expected to undergo continual refinement as a result of the evaluation.

The third and final subtask of Phase 3 is to integrate with currently available commercial systems those components of the prototype toolset which show the most promise for improving V & V. The results of the survey of commercial CASE systems and APSEs conducted in Phase 2 and the ongoing evaluation of the prototype tools will be used to determine appropriate commercial systems to target for integration.

"Control Structure Diagrams For Ada"

by

James H. Cross II
Auburn University

Sallie V. Sheppard
Texas A&M University

W. Homer Carlisle
Auburn University

Advances in hardware, particularly high-density bit-mapped monitors, have led to a renewed interest in graphical representation of software. Much of the research activity in the area of software visualization and computer-aided software engineering (CASE) tools has focused on architectural-level charts and diagrams.

However, the complex nature of the control constructs and the subsequent control flow defined by program design languages (PDLs), which are based on programming languages such as Ada, Pascal, and Modula-2, make detailed design specifications attractive candidates for graphical representation. And, since the source code itself will be read many times during the course of initial development, testing, and maintenance, it too should benefit from the use of an appropriate graphical notation.

The control structure diagram (CSD) is a notation intended specifically for the graphical representation of detailed designs, as well as actual source code. The primary purpose of the CSD is to reduce the time required to comprehend software by clearly depicting the control constructs and control flow at all relevant levels of abstraction, whether at the design level or within the source code itself. The CSD is a natural extension to existing architectural graphical representations such as data flow diagrams, structure charts, and Booch diagrams.

The CSD, initially created for Pascal/PDL [11], has been extended significantly so that the graphical constructs of the CSD map directly to the constructs of Ada. The rich set of control constructs in Ada (e.g., task rendezvous) and the wide acceptance of Ada/PDL by the software engineering community as a detailed design language made Ada a natural choice for the basis of a graphical notation. A major objective in the philosophy that guided the development of the CSD was that the graphical constructs supplement the code and PDL without disrupting their familiar appearance. That is, the CSD should appear to be a natural extension to the Ada constructs and, similarly, the Ada source code should appear to be a natural extension of the diagram. This has resulted in a concise, compact graphical notation that attempts to combine the best features of previous diagrams with those of well-established PDLs. A CSD generator was developed to automate the process of producing the CSD from Ada source code.
Background

Graphical representations have long been recognized as having an important impact in communicating from the perspective of both the “writer” and the “reader.” For software, this includes communicating requirements between users and designers and communicating design specifications between designers and implementors. However, there are additional areas where the potential of graphical notations have not been fully exploited. These include communicating the semantics of the actual implementation represented by the source code to personnel for the purposes of testing and maintenance, each of which are major resource sinks in the software lifecycle. In particular, Shelby et al. [2] found that code reading was the most cost-effective method of detecting errors during the verification process when compared to functional and structural testing. Standish [3] reported that program understanding may represent as much as 90% of the cost of maintenance. Hence, improved comprehension efficiency resulting from the integration of graphical notations and source code could have a significant impact on the overall cost of software production.

Since the flowchart was introduced in the mid-50s, numerous notations for representing algorithms have been proposed and utilized. Several authors have published notable books and papers that address the details of many of these (4–6). Tripp [5], for example, describes eighteen distinct notations that have been introduced since 1977, and Aoyama et al. [6] describe the popular diagrams used in Japan. In general, these diagrams have been strongly influenced by structured programming and thus contain control constructs for sequence, selection, and iteration. In addition, several contain explicit EXIT structures to allow single entry/multiple exit control flow through a block of code, as well as PARALLEL or concurrency constructs. However, none of the diagrams cited explicitly contains all of the control constructs found in Ada.

Graphical notations for representing software at the algorithmic level have been neglected, for the most part, by business and industry in the United States in favor of nongraphical PDLs. A lack of automated support and the results of several studies conducted in the 1970s that found no significant difference in the comprehension of algorithms represented by flowcharts and pseudocode (7) have been major factors in this underutilization. However, automation is now available in the form of numerous CASE tools, and recent empirical studies reported by Aoyama [6] and Scanlan [8] have concluded that graphical notations may indeed improve the comprehensibility and overall productivity of software. Scanlan’s study involved a well-controlled experiment in which deeply nested if-then-else constructs, represented in structured flowcharts and pseudocode, were read by intermediate-level students. Scores for the flowchart were significantly higher than those of the PDL. The statistical studies reported by Aoyama et al. involved several tree-structured diagrams (e.g., PAD, YACC II, and SPD) widely used in Japan that, in combination with their environments, have led to significant gains in productivity. The results of these recent studies suggest that the use of a graphical notation with appropriate automated support for Ada/PDL and Ada should provide significant increases in productivity over current nongraphical approaches.

The CSD for Ada is supported by an operational prototype graphical prettyprinter that accepts Ada source code as input and generates the CSD in a manner similar to text-based prettyprinters.

Control Structure Diagram

Figure 1(a) contains an Ada task body CONTROLLER adapted from [9] that loops through a priority list attempting to accept selectively a REQUEST with priority P. Upon on acceptance, some action is taken, followed by an exit from the priority list loop to restart the loop with the priority. In typical Ada task fashion, the priority list loop is contained in an outer infinite loop. This short example contains two threads of control: the rendezvous, which enters and exists at the accept statement, and the thread within the task body. In addition, the priority list loop contains two exits: the normal exit at the beginning of the loop when the priority list has been exhausted, and an explicit exit invoked within the select statement. While the concurrency and multiple exits are useful in modeling the solution, they do increase the effort required of the reader to comprehend the code.

Figure 1(b) shows the corresponding CSD generated by the graphical prettyprinter. In this example, the intuitive graphical constructs of the CSD clearly depict the point of rendezvous, the two nested loops, the se-
lect statement guarding the accept statement for the task, the unconditional exit from the inner loop, and the overall control flow of the task. When reading the code without the diagram, as shown in Figure 1(a), the control constructs and control paths are much less visible although the same structural and control information is available. As additional levels of nesting and increased physical separation of sequential components occur in code, the visibility of control constructs and control paths becomes increasingly obscure, and the effort required of the reader dramatically increases in the absence of the CSD.

Now that the CSD has been briefly introduced, the various CSD constructs for Ada are presented in Figure 2. Since the CSD is designed to supplement the semantics of the underlying Ada, each of the CSD constructs is self-explanatory and are presented without further description.

Automated Support — The CSD Graphical Prettyprinter

Automated support is a requirement, at least in the professional ranks, for widespread utilization of any graphical representation. Without automated support, diagrams are difficult to construct and maintain from the standpoint of “living” formal documentation, although software practitioners may use several types of diagrams informally during design and even implementation. Automated support comes in many forms, ranging from general-purpose “drawing aids” to automatic generation and maintenance based on changes to source code. The CSD for Ada is currently supported by an operational prototype graphical prettyprinter that accepts Ada source code as input and generates the CSD in a manner similar to text-based prettyprinters. The prototype was implemented under DEC’s VAX VMS using a scanner/parser generator and an Ada grammar. The user interface was built using DEC’s VAX Curses, and to provide the user with interactive viewing of the CSD, a special version of DEC’s EVE editor was generated. Custom fonts for the CSD graphics characters were built for both the VT220 terminal and the HP Laser Jet printer. Using font-oriented graphics characters rather than bit-mapped images provided for a high degree of efficiency in generating the diagrams.

The potential of the CSD is best realized during detailed design, implementation, verification, and maintenance.

Figure 2. Control structure diagram constructs for Ada.
The prototype is currently being ported to the Sun-4 workstation under UNIX and X Windows, where enhancements will include an option to collapse the diagram around any control constructs and an option to generate an intermediate level architectural diagram that indicates control structure among subprograms and tasks.

Conclusions and Directions

A new graphical tool that maps directly to Ada was formally defined and automated. The CSD offers advantages over previously available diagrams in that it combines the best features of PDL and code with simple intuitive graphical constructs. The potential of the CSD can be best realized during detailed design, implementation, verification, and maintenance. The CSD can be used as a natural extension to popular architectural-level representations such as data flow diagrams, Booch diagrams, and structure charts.

Our current reverse engineering project, GRASP/Ada [10], is focused on the generation of multilevel and multiview graphical representations from Ada source code. As indicated in GRASP/Ada overview shown in Figure 3, the CSD represents the code/PDL level diagram generated by the system. Our present efforts are concentrated on the extraction of architectural- and system-level diagrams such as structure charts, Booch diagrams, and data flow diagrams. The reverse engineering of graphical representations is destined to become an integral component of CASE tools, which until recently have focused on forward engineering. The development of tools that provide for interactive automatic updating of charts and diagrams will serve to improve the overall comprehensibility of software and, as a result, improve reliability and reduce the cost of software.

The reverse engineering of graphical representations is destined to become an integral component of CASE tools, which until recently have focused on forward engineering.

Figure 3. Overview of the GRASP/Ada reverse engineering project.
Acknowledgments

This research was supported, in part, by a grant from George C. Marshall Space Flight Center, NASA/MSFC, AL 35821. Richard Davis, Charles F. May, Kelly I. Morrison, Timothy Plunkett, Darren Tola, K.C. Waddel, and others made valuable contributions to this project.

He received a B.S. degree from the University of Houston, an M.S. degree from Sam Houston State University, and a Ph.D. from Texas A&M University.

Sallie V. Sheppard is the Associate Provost for Undergraduate Studies and Professor of Computer Science at Texas A&M University, College Station, TX. She received B.A. and M.S. degrees from Texas A&M University and a Ph.D. from the University of Pittsburgh. Her research interests include programming languages and simulation.

W. Homer Carlisle is an Assistant Professor of Computer Science and Engineering at Auburn University, Auburn, AL. He received B.A., M.A., and Ph.D. degrees from Emory University. His research interests include programming languages and parallel processing.
Appendix C

Extended Examples

The examples in this Appendix were extracted from a set of Ada source code files provided by NASA to test the CSD generator. These examples were used in Section 5 to illustrate the User Interface.

User Manual (MAN-Page)
NAME
graspada – (X Windows version) Graphical Representation of Algorithms, Structures, and Processes

SYNOPSIS
graspada

DESCRIPTION
graspada generates graphical representations for Ada programs. Currently these include Control Structure Diagrams (CSDs) for highlighting the program control structure. Object diagrams will be included in future versions. This manual is intended for use in conjuction with the GRASP/Ada tool.
xgrasp is written in C for the X Window System (Version 11, Release 4).

USAGE
When graspada is invoked, the GRASP/Ada System Window is created and the user positions it on the screen. The System Window allows the user to open Source Code editors or CSD viewers, generate CSDs, load the CSD font, browse the HELP system, or choose a printer. The System, Source Code, and CSD windows are described in greater detail below.

SYSTEM WINDOW
The System Window provides the user with the overall organization and structure of the GRASP/Ada tool. Option menus include: General, Source Code, Control Structure Diagram, and Help. These are briefly described below. A future menu is planned for Object Diagrams.

GRASP/Ada main window has four selectable buttons, three of which have associated submenus.

1. General
2. Source Code
3. Control Structure Diagram
4. Help

General:
This category of commands is concerned with environmental matters. This button has a submenu associated with it. Click with the select mouse button on the General button, and the submenu associated with General will pop up. If any of the following options is to be selected, drag the arrow with the select mouse button to that option and then release the mouse.

User Manual:
Not yet implemented

Set Printer:
If Set Printer option is selected, a window showing different printers will pop up. You can choose one of the available printers as a default printer. For example if you want to select "opal" as the default printer click on opal with select mouse button and click on OK button to confirm it. If you want to select some other printer other than those available on the printer menu, click on <Default> with select mouse button. Type the printer name in the corresponding printer name area. For example if you want to select "xyz" as the default printer, type 'lpr -Pxyz' in the printer name area (which is just right to <Default> button). Finally click on OK to confirm the selection with select mouse button. If you want to cancel the above selected option click on Cancel with select mouse button.

Set Compiler:
If this option is selected, a dialog window will pop up. You can type the command needed to
invoke the required Ada compiler. Click on OK to confirm the selection. Otherwise click on Cancel to cancel the selection.

Load Window Fonts:
Typically this option is unnecessary. The CSD window fonts are loaded into video memory upon invocation. If, however, during operation you get the message "The CSD font is not loaded", you must load it yourself. You can type the path name of the directory containing the CSD fonts. If CSD fonts are not already loaded, type the directory name which contains the CSD fonts. Confirm by clicking on OK button. Otherwise click on Cancel button to cancel the selection. If CSD fonts are already loaded, it will show a message saying "The CSD font is already loaded". Click on OK button to quit the pop up window.

Quit:
You can quit the GRASP/Ada tool by selecting this option. You will see a window displaying the message "Are you really sure you want to quit?". If you want to quit GRASP/Ada tool click on OK. Otherwise click on Cancel to cancel quit.

Source Code
This button has a submenu (Open text window, Close all text windows) associated with it. Click with the select mouse button on Source Code button. Submenu associated with Source Code will pop up. It has the following options. If any of the following options is to be selected, drag the select mouse button up to that option and then release the button.

Open text window:
A source code window containing a text editor for entering, loading, or modifying Ada source code will pop up. See the description of Source Window below.

Close all text windows:
Closes all the text windows.

Control Structure Diagram
This button has a submenu (Open CSD window, Close all CSD windows, Generate CSD...) associated with it. Click with the select mouse button on Control Structure Diagram button. Submenu associated with Control Structure Diagram will pop up. It has the following options. If any of the following options is to be selected, drag the select mouse button up to that option and then release the mouse.

Open CSD Window:
A CSD window containing a text editor for loading or modifying CSD file will pop up. See the description of CSD window below.

Close all CSD Windows:
Closes all the CSD windows.

Generate CSD...:
CSD Generation Options window will pop up. You can select the Ada source file and CSD file names by typing their names. You can use GRASP/Ada File Selector also to select the file names. If you want to select the Ada source file(s) using GRASP/Ada File Selector, click with the select mouse button on top Select button. GRASP/Ada File Selector window will pop up. The contents of different directories can be viewed by selecting different directories. If the contents of the Home directory are to be viewed, then click on Home button. If the contents of Root directory are to be viewed, then click on Root button. If the contents of the Parent directory (parent directory of the current directory) are to be viewed, then click on Parent
button. If the contents of any other directory are to be viewed, then select that directory by clicking on that directory name in directory contents view area. If you are not able to see the contents of the selected directory, click on scrollbar once. You should be able to view the contents of that directory (if there are some files or directories in that directory).

Finally, you can select a file for Control Structure Diagram generation by clicking on any file name in directory contents view area. Click on Select button to select that file name. Otherwise click on Cancel button to cancel file selection.

You can select number of files using wild card option. Suppose you want to generate the CSDs for four files, and their file names are Example1.a, Example2.a, Example3.a, Example4.a, and if these files are in the directory called grasp, select the directory grasp from directory contents view area. Then directory name will be shown as follows.

\[ \text{The Path/grasp} \]

Now type the wild card as follows
\[ \text{The Path/grasp/*.a} \]
\[ \quad \text{OR} \]
\[ \text{The Path/grasp/Exa*.a} \]
\[ \quad \text{OR} \]
\[ \text{The Path/grasp/Example?.a} \]

Then click with the select mouse button on Select button in GRASP/Ada File Selector window. The GRASP/Ada file selector window will be closed and Source file name(s) and CSD file name(s) are copied into Ada source file(s) and CSD file name(s) in CSD Generation Options window. Click with the select mouse button on Generate CSD in CSD Generation Options window to generate CSDs for all the above selected source file(s). Otherwise click on Cancel button to cancel the generation of CSDs. If Generate CSD is selected then following message will be shown in the message area of the Main window if you are generating CSDs using wild card option.

Source Directory: \text{The Path/grasp}

CSD Directory: \text{The Path/grasp}

<table>
<thead>
<tr>
<th>Source File</th>
<th>CSD File</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example1.a</td>
<td>Example1.a.csd</td>
<td></td>
</tr>
<tr>
<td>Example2.a</td>
<td>Example2.a.csd</td>
<td></td>
</tr>
<tr>
<td>Example3.a</td>
<td>Example3.a.csd</td>
<td></td>
</tr>
<tr>
<td>Example4.a</td>
<td>Example4.a.csd</td>
<td></td>
</tr>
</tbody>
</table>

Total number of files are 4.

Help

Click on Help (in main window) with the select mouse button. The Help window displays a list of the CSD constructs for Ada and a second window to display the corresponding CSD construct. Click with the select mouse button on PRINT ALL DIAGRAMS to print all the CSD constructs to the selected printer. Click on DISPLAY ALL CSD CONSTRUCTS to see all the constructs in the second window. These constructs are arranged in alphabetical order. Drag scrollbar to view different constructs. Click on individual construct to view individual construct. Finally, click on Quit with the select mouse button to quit the help window.
SOURCE WINDOW

This window has three selectable buttons.

File

Click with the select mouse button on File button and the submenu (Load, Generate CSD, Save, Save as... Print, Quit) associated with File will pop up. To select one of the options, drag the select mouse button up to that option and then release the mouse.

Load:
GRASP/Ada File Selector window showing the name and contents of the current directory (The directory from which GRASP/Ada is invoked) will pop up. The contents of different directories can be viewed by selecting different directories. If the contents of the Home directory are to be viewed, then click on Home button. If the contents of Root directory are to be viewed, then click on Root button. If the contents of the Parent directory (parent directory of the current directory) are to be viewed, then click on Parent button. If the contents of any other directory are to be viewed, then select that directory by clicking on that directory name in directory contents view area. If you are not able to see the contents of the selected directory click on scrollbar once. You should be able to view the contents of that directory (if there are some files or directories in that directory). Like this you can view contents of any directory. Finally, you can select a file for Control Structure Diagram generation by clicking on any file name in directory contents view area. Click on Select button to select that file name. Otherwise click on Cancel button to cancel file selection.

Generate CSD:
After selecting a source file using above mentioned Load option, Control Structure Diagram can be generated for that source file by selecting this option. When this option is selected, a CSD window containing Control Structure Diagram will pop up. See the description of CSD window.

Save:
The Ada file will be saved with the existing file name. If you want to save it as a different file name, select Save as... option.

Save as...:
A dialog window will pop up. You can type the file name as which the existing Ada file has to be saved and click on OK to confirm the selection. Click on Cancel to cancel the selection. You can select the file name from GRASP/Ada file selector window also by clicking on Select button.

Print:
A window showing different options for printing will pop up. The default file name will be existing file in the Source Window. If you want to print any other Ada file, you can select that file either by typing the file name in the file name area or you can select the Ada file name using GRASP/Ada File Selector by clicking with the select mouse button on Select button.

View  Not yet implemented.

Find  Not yet implemented.

CSD WINDIW
This window has four (File, View, Find, Font) selectable buttons.
File

Click with the select mouse button on File button and the submenu (Load, Open Source, Generate CSD, Compile, Save, Save as..., Print, Quit) associated with File will pop up. To select one of the options, drag the select mouse button up to that option and then release the mouse.

Load:
GRASP/Ada File Selector window showing the name and contents of the current directory (The directory from which GRASP/Ada is invoked) will pop up. The contents of different directories can be viewed by selecting different directories. If the contents of the Home directory are to be viewed, then click on Home button. If the contents of Root directory are to be viewed, then click on Root button. If the contents of the Parent directory (parent directory of the current directory) are to be viewed, then click on Parent button. If the contents of any other directory are to be viewed, then select that directory by clicking on that directory name in directory contents view area. If you are not able to see the contents of the selected directory click on scrollbar once. You should be able to view the contents of that directory (if there are some files or directories in that directory). Like this you can view contents of any directory. Finally, you can select a file for Control Structure Diagram generation by clicking on any file name in directory contents view area. Click on Select button to select that file name. Otherwise click on Cancel button to cancel file selection.

Open Source:
Not yet implemented.

Generate CSD:
Not yet implemented.

Compile:
Not yet implemented.

Save:
The CSD file will be saved. The default file name will be SourceFileName.csd. If you want to save it as a different file name, select Save as... option.

Save as...:
A dialog window will pop up. You can type the file name as which the existing CSD file has to be saved and click on OK to confirm the selection. Click on Cancel to cancel the selection. You can select the file name from GRASP/Ada file selector window also by clicking on Select button.

Print:
A window showing different options for printing will pop up. The default file name will be SourceFileName.csd. If you want to print any other CSD file, you can select that file either by typing the file name in the file name area or you can select the CSD file name using GRASP/Ada File Selector by clicking with the select mouse button on Select button.

You can select either of the options Yes or NO by clicking with the select mouse button to print header. The default header is GRASP/Ada v3.0. You can change this default header by typing the required header in header text area. You can select either of the options Yes or No by clicking with the select mouse button to print page numbers. The default point size is 10. The default size can be changed by typing required size in Point size area. Finally click on Print button with the select mouse button to print the CSD file to a selected printer. If the printer is not already selected, select the printer name from General submenu. If you want to
cancel the print job, click with select mouse button on Cancel button.

Quit:
Quit the CSD window.

View Not yet implemented.

Find Not yet implemented.

Font Control Structure Diagram can be viewed in different sizes of fonts. Click with select mouse button on Font button. It displays different sizes (csd09, csd11, csd13, csd15, csd18) of the available fonts. CSDs can be viewed in any of the available fonts by selecting that font.

WIDGETS
In order to specify resources, it is useful to know the hierarchy of the widgets which compose graspada. In the notation below, indentation indicates hierarchical structure. The widget class name is given first, followed by the widget instance name.

Xgasp graspada
  Form myform
    Label mylabel
    MenuButton mymenu
      SimpleMenu Generalmenu
        SmeBSB User Manual
        SmeBSB Environment
        SmeBSB Load window fonts
        ...
        (one for each menu)
    Command mycommand
  TransientShell GRA
    Form GRA
    Form GRA
      Command GRA
      Command GRA
      Command GRA
      Command GRA
    Label GRA
    Viewport GRA
    List GRA

ENVIRONMENT
GRASP_HOME
Must be set to the root directory of the GRASP/Ada system. graspada uses this environment variable to locate the CSD fonts and the HELP system files.

MANPATH
If the GRASP/Ada system man page is not installed with the other man pages, this environment variable must be modified to point to the directory containing it, which is $GRASP_HOME/man.

PATH
Must be set to point to the graspada executable, which is located in $GRASP_HOME/bin.
XENVIRONMENT
Specifies the name of a resource file that overrides the global resources used in the GRASP/Ada X Window System interface.

EXAMPLES
FILES
  ~graspada/bin/graspada
  ~graspada/lib/Help help files
  ~graspada/lib/fonts font files
  ~graspada/man/mann/graspada.1 (Man page)

AUTHORS
The development of graspada was directed by Dr. James H. Cross II at Auburn University. The project was supported, in part, by a grant from George C. Marshall Space Flight Center, NASA/MSFC.

The Control Structure Diagram was created by Dr. Cross. The parser, scanner, and semantic actions for creating the CSD for Ada were written by Charles H. May. The PostScript CSD font and X11R4 BDF CSD fonts were created by Timothy A. Plunkett. The X Window System interface was written by Kelly I. Morrison and Darren Tola. The HELP system was written by Narayana S. Rekapalli. Richard Davis, Kathryn C. Waddel, and others made valuable contributions to this project.

Ada is a trademark of the United States Government, Ada Joint Program Office.

PostScript is a trademark of Adobe Systems, Inc.
